In southeastern Venezuela, malaria cases have increased since 2013. We found that 46% of 352 blood samples from symptomatic patients in 1 municipality tested positive for Plasmodium spp. In addition, the number of cases increased by 10 times in 4 years (2014–2017) and by 3 times in 1 year (2016–2017).

This finding was not unexpected, as a number of studies that use molecular techniques to detect blood parasites in carnivores report similar findings [86, 87]. It is possible that the low prevalence of Ehrlichia parasites and/or the small sample size of most studies limit the detection of Ehrlichia presence in the host population.

is able to detect parasites at low titer, generally below 5 parasites/μl of blood for all five human Plasmodium para-sites [3,7-9,11]. Amongst these molecular assays, nested PCR [4-6] targeting 18S ssu rRNA genes of all five human malaria parasites has been considered the molecular gold standard for malaria detection. However, due to the cum-
