It has been known for half a century that neurotransmitters are released in preformed quanta, that the quanta represent transmitter-storing vesicles, and that release occurs by exocytosis. The focus of this book is twofold. In the first part, the molecular events of exocytosis are analysed. This includes a discussion of presynaptic calcium channels, the core proteins of the secretory machinery, and the actions of clostridial toxins and a -latrotoxin, famous for their potency as well as their ...

3k Downloads. Part of the Handbook of Experimental Pharmacology book series (HEP, volume 184) Neurons send out a multitude of chemical signals, called neurotransmitters, to communicate between neurons in brain, and between neurons and target cells in the periphery. The most important of these communication processes is synaptic transmission, which accounts for the ability of the brain to rapidly process information, and which is characterized by the fast and localized transfer of a signal ...

Neurotransmitters are chemical compounds released by neurons after depolarization that act on other neurons to produce a response (Fig. 3). The response produced by a neurotransmitter is mediated by a neurotransmitter receptor capable of recognizing it. Neurotransmitters are the principal means by which neurons transfer information to each other.

Neurotransmitters Synaptic transmission relies on local synthesis, and release of neurotransmitter molecules at the synapse, binding of the neurotransmitter to its cognate post-synaptic receptor (s) and inactivation/removal of the neurotransmitter from the synaptic space to terminate the activation.

The release of neurotransmitters at the presynaptic neuron and the subsequent activation of postsynaptic receptors lead to stimulation or inhibition of neuronal transmission. The excitatory neurotransmission involves depolarization of the postsynaptic neuron or cell due to a decrease in the polarity of the cells by the influx of cations such as sodium ions.

The discovery of dopamine in 1957-8 was one of the seminal events in the development of modern neuroscience, and has been extremely important for the development of modern therapies of neurological and psychiatric disorders. Dopamine has a fundamental role in almost all aspects of behavior — from motor control to mood regulation, cognition and addiction and reward — and dopamine research ...
